## ABSTRACT

**Background:** Different therapeutic regimens were used for eradication of *Helicobacter pylori*, based on the cost, effectiveness and patient's compliance. The aim of this study was the evaluation of licorice compared with bismuth in quadruple regimen on eradication of *H. pylori* in patients with peptic ulcer disease (PUD). **Materials and Methods:** In a double-blind clinical trial study, 60 patients with PUD and positive rapid urease test were enrolled. The patients were randomly allocated into two equal groups. In first group, licorice, amoxicillin, metronidazole and omeprazole and in the second (control) group, bismuth subsalicylate, amoxicillin, metronidazole and omeprazole were prescribed respectively, and 4 weeks after treatment, in order to evaluate *H. pylori* eradication, urea breath test was done in all patients. The outcome of the study was the preference usage of licorice as an effective medication for *H. pylori* eradication. **Results:** Mean age of the patients in the control and case groups were  $40.8 \pm 15.5$  and  $42.2 \pm 15.8$  years, respectively ( $P = 0.726$ ). Seventeen (56.7%) patients in control group and 16 (53.3%) in the case group were female ( $P = 0.795$ ). Both groups were similar based on frequency of gastric or duodenal ulcer. Response to treatment were seen in 20 (67%) and 17 (57%) patients of case and control groups, respectively ( $P > 0.05$ ). **Conclusion:** Our study showed that licorice is as effective as bismuth in *H. pylori* eradication; therefore, in patients whom bismuth is contraindicated, licorice can be used safely instead.

**Key words:** Bismuth, *Helicobacter pylori* eradication, licorice

## INTRODUCTION

Peptic ulcer disease (PUD) is a common and treatable disease worldwide<sup>[1]</sup> which without eradication of *Helicobacter pylori* infection, 50-80% recurrence rate will be appeared during the 6-12 months after initial ulcer healing.<sup>[2]</sup> Esophago-gastro-duodenoscopy (upper endoscopy) is the gold standard method for exact diagnosis of PUD which its accuracy depends on the location of the ulcer and the experience of the endoscopist.<sup>[3]</sup> PUD can present as epigastric pain or dyspepsia. Dyspepsia is a common and occasionally life-threatening clinical problem. The symptoms of ulcer and nonulcers dyspepsia may be similar. In fact, in endoscopy, the most common diagnosis is functional dyspepsia, but other problems such as ulcer disease or gastric cancer may also be seen.<sup>[4]</sup> Functional

dyspepsia is likely, if symptoms persist after an initial negative investigation. There is not clear relationship between functional dyspepsia and *H. pylori* infection, although in *H. pylori* positive patients, improvement of symptoms may be observed in about 15% of the patients after eradication treatment.<sup>[5]</sup>

Multiple regimens have been evaluated for *H. pylori* eradication in randomized controlled trials;<sup>[6,7]</sup> however, despite these studies, the optimal modality of treatment has not been defined yet, due to increasing risk of resistance to treatment.<sup>[8]</sup> The selected treatment regimen should be effective, as well as considering some issues such as side effects, cost, the number of drugs and duration of treatment.<sup>[7]</sup>

Bismuth subsalicylate can inhibit growth or eradicate *H. pylori in vitro*; however, its minimal inhibitory concentration (MIC) is high.<sup>[9]</sup> Bismuth subsalicylate is effective for suppression of *H. pylori* as mono-therapy but combination with other antibiotics could increase its

efficacy.<sup>[10]</sup> Licorice (*Glycyrrhiza glabra*) has been used since many years ago for relieving of epigastric pain, and healing of gastric ulcers.<sup>[11]</sup> It stimulates the production of mucus membrane, and may cause symptomatic improvements of peptic ulcer. Moreover, licorice might inhibit leukotriene synthesis and prostaglandin; however, it may also stimulate of adrenocortical axis by inhibition of 11- $\beta$  hydroxyl steroid dehydrogenase.<sup>[12]</sup> *In vitro* antibacterial and antiviral effect of licorice was shown in some studies,<sup>[13,14]</sup> but by our knowledge there was not any clinical study about anti *H. pylori* effect of licorice in the patients, so the aim of this study was the evaluation of effect of licorice as one component of quadruple therapy for *H. pylori* eradication in the patients with dyspepsia.

## MATERIALS AND METHODS

In a double-blind clinical trial, 60 patients who referred to endoscopy center of Hajar Hospital in Shahrekord (located at Southwest of Iran) were enrolled. Inclusion criteria were: Existence of abdominal pain or dyspepsia and gastric ulcer, duodenal ulcer, gastritis or duodenitis in upper endoscopy and *H. pylori* positivity in biopsy specimen by rapid urease test. Exclusion criteria were: Noncooperation of the patients during the study, adverse effects of medications during the study, and having liver or renal failure history. The sample size was determined based on availability of patients and our budget limitation. The patients randomly entered into two groups of 30 patients. Two groups were matched based on age, gender, history of cigarette smoking and PUD. While in Group 1 (case group), the patients were treated with metronidazole tablet 500 mg/twice a day bid, amoxicillin 1 g/bid, omeprazole 20 mg/bid and D-Reglis (containing 380 mg licorice/tablet)/bid “manufactured by Irandaruc Pharmacy Company”, in control group, bismuth subsalicylate, 262 mg/tablet (2 tablet/bid) were prescribed instead of licorice. Urea breath test was done for all patients 4 weeks after the end of treatment (by Heliprobe machine, Kibion company, Sweden). Drug regimen was prescribed by Gastroenterologist and evaluation of the patients was done by a resident.

The primary outcome of this study was to evaluate the effect of licorice on *H. pylori* eradication and secondary outcome was the use of licorice as an effective and safe medication in the combination regimen of PUD treatment. Patients' data were collected by check list and was entered into SPSS 17 (SPSS Inc., Chicago, IL, USA) and were analyzed by using *t*-test, Chi-square and Fisher's exact test. All data and information were confidential and an informed consent was taken from every patient for obtaining samples and other processes of the study. The study was approved

by Ethics Committee of Shahrekord University of Medical sciences.

## RESULTS

Mean age of the patients in the control and case groups were  $40.8 \pm 15.5$  and  $42.2 \pm 15.8$  years, respectively with no significant difference between two groups ( $P = 0.726$ ). Seventeen (56.7%) patients in control group and 16 (53.3%) in case group were female ( $P = 0.795$ ). Table 1 shows the main characteristics of participants. Sixteen patients were smoker ( $P = 0.243$ ), three patients had history of PUD. There was also history of dyspepsia in 30 patients ( $P = 0.606$ ). Endoscopy showed gastric ulcer, duodenal ulcer, gastritis and duodenitis in 4, 12, 51 and 23 patients, respectively ( $P > 0.05$ ). History of nonsteroid antiinflammatory drugs consumption was seen in 12 patients ( $P = 0.197$ ).

**Table 1: Some criteria of the patients of case and control group**

	Number (%)		P
	Licorice-quadruple treatment	Bismuth-quadruple treatment	
History of PUD			
Positive	2 (6.7)	1 (3.3)	0.555
Negative	28 (93.3)	29 (96.7)	
Cigarette smoking			
Positive	10 (33.3)	6 (20)	0.243
Negative	20 (66.7)	24 (80)

NSAID=Nonsteroid antiinflammatory drugs; PUD=Peptic ulcer disease

**Table 2: Frequency of response to treatment in the case and control group**

Urea breath test (posttreatment)	Number (%)		P
	Licorice-quadruple treatment	Bismuth-quadruple treatment	
Positive	10 (23.3)	13 (43.3)	0.428
Negative	20 (66.7)	17 (56.7)	

The response to treatment (eradication of *H. pylori*) was shown in Table 2, with 20 (67%) and 17 (57%) patients among case and control groups, respectively (0.428). There were not any side effects or interactions (such as severe hypertension, muscular weakness or diarrhea), during the study tending to discontinuation of treatment.

## DISCUSSION

This study showed that low dose of licorice (380 mg/bid) against *H. pylori* in quadruple therapy could be as effective as bismuth. After endoscopy, there was no difference between two groups based on duodenal ulcer, gastric ulcer, duodenitis or gastritis. In addition, response to treatment in patients of two groups was similar.

Almost one-third of patients with dyspepsia may have PUD. In addition, due to susceptibility of these patients to the development of gastric adenocarcinoma, eradication treatment might be recommended in these patients. Hence, treatment of *H. pylori* infection should be considered in patients with gastric or duodenal ulcer, although eradication of *H. pylori* in nonulcer dyspepsia remains debatable.<sup>[15-17]</sup> Furthermore, various regimens have been used for *H. pylori* eradication with success rate of 75-80%.<sup>[18]</sup> In our study, the patients were under treatment of traditional quadruple therapy against *H. pylori* because of high efficacy, low price, and minimal side-effects of this regimen.

Anti *H. pylori* and gastric mucosal protective effect of licorice and bismuth is somewhat similar,<sup>[19]</sup> therefore we used licorice (D-reglis) instead of bismuth in traditional quadruple therapy, and showed that licorice is at least as efficient as bismuth in quadruple regimen for *H. pylori* eradication. Antimicrobial effect of licorice has been evaluated in some studies such as the study of Tsukiyama, which found that licorice was effective against Gram-positive bacteria and especially against all *Bacillus* species.<sup>[13]</sup> In addition, Fukai showed the effectiveness of licorice against methicillin-resistant *Staphylococcus aureus*.<sup>[20]</sup> In a review article, Bouras described many therapeutic effects of licorice, such as anti-PUD and gastric mucosal protection, antimicrobial and antiviral property, antitumor and antiinflammatory effects, decreasing of low density lipoprotein cholesterol and improvement of sore throat.<sup>[21]</sup>

In a few studies, anti *H. pylori* effect of licorice were evaluated *in vitro*, for example Nariman showed that licorice could be effective against *H. pylori*.<sup>[22]</sup> Moreover, Fukai proved its anti *H. pylori* effect and concluded that licorice may be useful for prevention of peptic ulcer or

gastric cancer in *H. pylori*-infected patients.<sup>[14]</sup> Jafarian *et al.* evaluated anti *H. pylori* effect of licorice on isolated strains from gastric biopsy of the patients, and concluded that none of strains had resistance to the licorice extracts. In fact, *H. pylori* may show susceptibility to licorice extract in MIC (The MIC was defined as the lowest concentration of a drug that completely inhibited the growth on the agar plates) that is achievable in the stomach under therapeutic concentration. As licorice had not adverse effects on the normal bacterial flora of gastrointestinal tract, therefore the authors suggested that licorice extract may be an effective agent for the treatment of all forms of *H. pylori* spores *in vivo*, due to susceptibility of all *H. pylori* strains to licorice extracts.<sup>[23]</sup> Similar results were obtained by Krause *et al.* which showed bactericidal activity of licorice to kill all the five strains of *H. pylori* rapidly; they suggested its using as an alternative agent in clarithromycin-resistant strains of *H. pylori*.<sup>[24]</sup> In another study, Aly *et al.* evaluated antiinflammatory effect of licorice and concluded that licorice can increase antiinflammatory effect of Na diclofenac as well as adding antiulcer property.<sup>[25]</sup> Beil *et al.* also approved antiinflammatory and anti *H. pylori* effect of two flavonoids of licorice that stimulated production of prostaglandin E2 in isolated gastric mucosal cells, and inhibited growth of *H. pylori* in culture media; therefore they suggested consumption of licorice in the patients with gastrointestinal diseases associated with *H. pylori* infection.<sup>[26]</sup> Usual recommended dose by Producer Company for D-reglis in PUD is two tablets, 2 or 3 times/day, however; in this study lower dose of drug was effective too. This dosage of licorice is associated with lower side effect as in this study, and none of patients had any complication of treatment. Krahenbuhl also showed that the use of less than 500 mg of glicirinic acid daily had minimal and transient effect on blood pressure elevation, but larger amounts could lead to permanent side effects.<sup>[27]</sup> Furthermore, all previous studies on anti *H. pylori* effect of licorice were done *in vitro* and in laboratory environment. Antimicrobial effect of antibiotics *in vivo* in the acidic condition of stomach may be different from their efficacy in medium in laboratory, for example amoxicillin is a very potent anti *H. pylori in vitro* but its effect significantly decreased in acidic PH of stomach.<sup>[28]</sup>

Our study has several limitations such as small sample size, short duration of follow-up and lack of control group with placebo consumption. Therefore, we recommend conducting studies with larger sample size, longer duration of follow-up for detection of recurrence and use of third group with placebo and finally use of licorice in other therapeutic modality such as triple regimen.

## CONCLUSION

Licorice is a safe, inexpensive and effective agent for *H. pylori* eradication in quadruple regimen, so we could use it in some conditions such as ones with intolerance or contraindication of Bismuth use. Meanwhile, it may also be effective in resistant strains or recurrent PUD.

## ACKNOWLEDGMENT

The authors acknowledge all staff of Hajar Endoscopy Center for their cooperation in this study.
